Hello Everyone

My name is Pranav Anand

and the website I'm working on is called Pomodoro.

Pomodoro is a study technique that splits a study session into multiple small focus sessions instead of one long drawn out study session.

So, usually it is a 25 minute study session followed by a five minute break and after four of such sessions, the person using the technique is allowed a 15 minute long break. My website implements this technique and that's the main focus of the website.

There are other websites like this that I've used in the past. One is pomofocus.io and it works really well. The users of my website will mostly be students or teachers or anyone in the educational field- where learning is required.

But it can be used by anyone because I think learning is required by humans in general. My website also has a lot of other small but unique features that give it more of an edge compared to other Pomodoro websites. One of these that I've implemented is a notes feature which is connected to a local datbase. The whole webite has a local database connected to it.

One of it's unique features is that you can host it locally so it's private- so no one has your data. So coming back to one of the features- it's notes taking, so you can take the notes and save the notes of whatever during your focus session.

Secondly there's a task scheduler, you can specify what task, what time, what data- in how much time you want it done and when you want it done. You can specify it on the task column on the side and you can assign each focus session to each specified task.

Thirdly there's a stats recording part of the website so it shows for how long you focused- how long u focused on say Monday, Tuesday, Wednesday. There's a calendar showing the time you focused on throughout the week, your daily average so on and so forth. So if you'd like to improve by seeing how much you've been focusing how much you should focus that's there as well.

The tech stack it uses is Python and it uses Flask so it's hosted on a Flask server locally and if I have to make it public I'll either make it completely static and upload it onto GitHub pages or use Render and upload it with the Python server. Even the datbase is hosted on Flask as well.

The frontend is html with javascript for a few of the finer workings like the timer and whatnot and the styling is done through CSS.

Thank you very much.
